

Info-gap assessment of cost-effectiveness for flood-mitigation scenarios: Haigh Beck case study

Onno Bokhove, School of Mathematics/Leeds Institute for Fluid Dynamics, Leeds, UK

Haigh Beck & graphical cost-effectiveness tool

Goal: value unvalued co-benefits Nature-Based Solutions (NBS)! Case study: Urban Haigh Beck runs 2000m from spring to River Aire with 100m drop, flows into/under canal, Surface flooding in neighborhoods near river & canal at ~1:15vrs AEP. New flood defense walls near river cover 1:200vrs AEP but trap beck; limited pump action $Q_7=0.245$ m³/s. Canal segment for large flood storage between locks is 7.5kmx10mx1.5m with several overflows. Combined Sewer Overflow (CSO) pollutes beck.

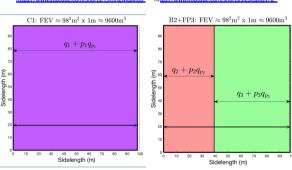

Flooding, polluted, 06-05-2024 of 6 Bradford apartments (~1:15vrs AEP):

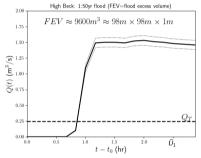

Haigh Beck-canal-Dyehouse Mill

canal-apartments of Mill

Flood-mitigation scenarios shown in square-lake graphs [1,2,3,4]: C1 canal: beck diverted into canal, automated gate to divide water into canal/culvert, coverage of α xFEV with α >1, costs q_1+p_1 q_{p1} , excess FEV coverage. Benefits Nature-Based Solutions: anti-drought, clean canal, extra storage for climate change; split CSO spills from beck to limit/cut Combined Sewer Overflows; extra costs: -B₁₁=q_{1CSO}.

B2+FP3 bund & flood-plain storage: 1.0xFEV. B2 upstream bund: in flatter areas, partial prevention α_2 xFEV with α_2 =0.4, costs q_2 + p_2 q_{p2} . FP3 culvert from canal to river opened at playing fields (protective flood plains), pumping needed, partial prevention α_3 xFEV with α_3 =0.6, costs q_3 + p_3 q_{p3} .

Flood—Excess Volume (FEV) is volume that causes damage [1]; ~numerical modelling (LCC/BMDC) 1:50yrs Haigh Beck flood: $FEV = \int_{t}^{t_0+T} Q(t) - QT dt = 9600 \text{m}^3 = 98 \times 98 \times 1 \text{m}^3 \text{ sense of size!}$

Measure	Base cost $q_i(k£)$	Probability p _i (/50yrs)	Damage $q_{p_i}(k\mathbf{\pounds})$	Total (k£)
C1 B2 FP3 B2+FP3	500(900) 385 400	1 0.25 0.05	70 200 200 -	570(970) 435 410 845

Base costs, probabilities & damage costs:

To obtain estimate for q_{n1}, start from £ 1.7M repair costs of a culvert breach, emptying 60km of the Leeds-Liverpool canal (2021-2022 CRT). Since the canal stretch involved in C1 is 7km, 1/8 of those costs are involved so ~ £ 210k, of which £ 140k are standard costs occurring even in the absence of flood storage in the canal, so £ 70k extra investment. Base costs: C1 q₁= £ 500k, plus extra costs for (optional) 200m pipeline to separate CSO from beck £ 400k (clean-up). Actual figures dificult to obtain in real cases (~10xFOIs!), q₂+q₃=785k given; other figures estimated, e.g., q_{p2}=q_{p3}= £ 200k, see Table above.

Utility functions u_1 and u_2 :

 $u_1 = \sum_{j=1}^2 w_j C_j$ without co-benefits, weights w_j =0,1. **B2+FP3** best. $u_2 = \sum_{i=1}^2 w_i C_i - \sum_{k=1}^{N_j} a_{jk} B_{jk}$ with co-benefits B_{jk} , B_{2k} =0, N_1 =5. Take $B_{11} = -q_{1CSO} = £ 400k$ (no pollution beck/clean canal).

But value benefits unknown: B_{12} = q_{1cc} (extra climate-change canal storage); $B_{13} = q_{1D}$ (drought benefits beck flow into canal); $B_{14} = q_{1E}$ (ecological value beck water in canal); $B_{15} = q_{1clean}$ (clean beck & canal). Difference D= £ 125k costs C1 (w. CSO) - (B2+FP3). When we are willing to assign combined benefits $B_1 = \sum_{k=2}^{N_1} B_{1k} > D$ in 50yrs, scenario C1 becomes best: break-even £ 2.5k p/a

Info-gap theory values NBS co-benefits!

Info-gap decision theory (Ben-Haim [5]) consists of three components: (i) Costs $\tilde{U}_1=C_1+p_1q_{p_1}+\alpha_{11}q_{1CSO}-\alpha_1B_1, \ \tilde{U}_2=C_2+p_2q_{p_2}+p_3q_{p_3}$ benefits combined into B₁, $\alpha_{11}=\alpha_1$ =1, i.e., models U_{ν} U_2 for scenarios C1 and B2+FP3. (ii) Performance requirements $m_i(h) < C_s$, costs & uncertainty models $I_1(h)$, $I_2(h)$ for C1, B2+FP3: $m_1(h) = \tilde{U}_1 - \alpha_1 h s_1 \leq C_s$, $\tilde{U}_1 = C_1 + p_1 q_{p_1} + \alpha_{11} q_{1CSO}$

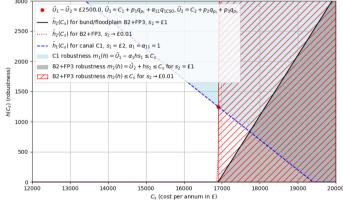

$$m_2(2) = \tilde{U}_2 + hs_2 \le C_s, \quad \tilde{U}_2 = C_2 + p_2q_{p_2} + p_3q_{p_3}$$

 $l_1(h) = \frac{|B_1|}{s_1} \le h, \quad l_2(h) = \frac{|U_2 - \tilde{U}_2|}{s_2} \le h$

Hence:
$$h = \frac{(\tilde{U}_1 - C_s)}{\alpha_1 s_1} \ge 0$$
, $h = \frac{(C_s - \tilde{U}_2)}{s_2} \ge 0$ (see graph below).

(iii) Performance aspiration or opportuneness [5,6] $\tilde{U}_2 - \beta s_2 \le C_w$, $\tilde{U}_1 + \alpha_1 \beta s_1 \le C_w$

Robustness curves for Haigh Beck flood-mitigation scenarios C1 and B2+FP3, 50 yr write-off • $\tilde{U}_1 - \tilde{U}_2 = £2500.0$, $\tilde{U}_1 = C_1 + p_1q_{p_1} + \alpha_{11}q_{1CSO}$, $\tilde{U}_2 = C_2 + p_2q_{p_2} + p_3q_{p_3}$

Discussion: C1 has factually unvalued co-benefits but costs higher than those of B2+FP3 (starting point of lines at h=0). For known costs of B2+FP3 such that $s_2 \rightarrow 0$, red dot at crossover sets value of £ 2.5k p/a, quantifying co-benefits. C1 can be more robust than B2+FP3 Decision-makers decide whether co-benefits worth extra money. Critique: Info-gap vs. Bayesian analysis? Outcome: unvalued NBS benefits can be valued robustly!
